### **Preface**

This guide provides a single location with everything you need to know about configuring and using True Cache.

### **Documentation Accessibility**

For information about Oracle's commitment to accessibility, visit the Oracle Accessibility Program website at http://www.oracle.com/pls/topic/lookup?ctx=acc&id=docacc.

#### **Access to Oracle Support**

Oracle customer access to and use of Oracle support services will be pursuant to the terms and conditions specified in their Oracle order for the applicable services.

### **Related Documents**

The following documents contain information that may be of use when configuring and using True Cache.

### Conventions

The following text conventions are used in this document:

Convention	Meaning
boldface	Boldface type indicates graphical user interface elements associated with an action, or terms defined in text or the glossary.
italic	Italic type indicates book titles, emphasis, or placeholder variables for which you supply particular values.
monospace	Monospace type indicates commands within a paragraph, URLs, code in examples, text that appears on the screen, or text that you enter.

1

### Overview of Oracle True Cache

Oracle True Cache is an in-memory, consistent, and automatically managed SQL and key-value (object or JSON) cache for Oracle Database.

For an interactive tour, see Oracle True Cache Technical Architecture.

### 1.1 About Oracle True Cache

True Cache is an in-memory, read-only cache in front of an Oracle database.

Like Oracle Active Data Guard, True Cache is a fully functional, read-only replica of the primary database, except that it's mostly diskless.

Modern applications often require a high number of connections and fast, low-latency access to the data. A popular approach is to place caches in front of the database because applications typically perform many more reads than updates, and they can read from the cache without affecting the database performance. For example, an airline reservation system reads data frequently as people shop for flights, and it's okay if the data isn't the most current compared to what's in the database. The application only needs to access the most current data when someone reserves a flight.

Unlike conventional caches, True Cache automatically keeps the most frequently accessed data in the cache, and it keeps the cache consistent with the primary database, other objects in the same cache, and other caches. It caches all Oracle Database objects and data types, including JSON.

Because True Cache implements Oracle Database security policies, you can control access to the cache. This enables you to cache sensitive data, like private personal information, that you might not ordinarily cache.

### 1.2 Benefits of Oracle True Cache

Oracle True Cache provides several business benefits related to application development and performance.

- Improves scalability and performance by offloading queries from the primary database.
- Reduces application response time and network latency by deploying True Cache closer to the application. This especially benefits situations where a database is in a different location than the application due to data residency requirements.
- Creates a large, in-memory storage area by dividing data across multiple True Caches.
   The total size of the cached data across all True Caches can be much larger than it would be for a single primary database or cache.
- Automatically maintains the cache contents.
- Simplifies development and maintenance by being transparent to the application.

### 1.3 How True Cache Works

At a high level, here's how Oracle True Cache works.

- An application decides whether to query data from True Cache or the primary database.
   For details on how this works, see Application Usage Models.
- True Cache satisfies queries by using data that's cached in its memory. When the data isn't in the cache, True Cache fetches the data from the primary database.
- True Cache is empty when it starts up, so it reads large chunks of data to populate the
  cache. After a block is cached, it's updated automatically through redo apply from the
  primary database. This is similar to the update mechanism used in Oracle Active Data
  Guard.
- A query to True Cache returns only committed data, and the data is always consistent.
- Like all caches, the True Cache data might not be the most current data as it exists in the primary database.
- If multiple True Caches exist and serve the same database application service, the listener automatically distributes and load balances sessions to each cache.

### 1.4 Considerations for Using True Cache

Consider these points when deciding whether to use Oracle True Cache.

- You need to configure enough memory for True Cache so your most frequently accessed data will stay in memory.
- True Cache only needs a small amount of storage for the standby redo log files.
   Configuration files like control files, the SPFILE, and temporary data files are automatically created.
- True Cache is a read-only cache, so you can't directly update the cache, but you can use DML redirection to indirectly update the cache.

#### **Related Topics**

Enabling DML Redirection

True Cache is a read-only cache, so you can't directly update the cache, but you can use DML redirection to indirectly update the cache.

### 1.5 Application Usage Models

Applications can use True Cache in two ways.

- The application maintains *two physical connections*: one to the primary database and one to True Cache. Each connection has a database application service, and the application chooses which connection to use based on whether it's reading or writing. You can use this model with any existing client drivers and any programming language.
  - The application sends queries that don't need to see the most current data to True Cache through a True Cache database application service. The application sends other queries and updates to the primary database through the primary database application service.
- The application maintains one logical connection that uses the database application service for the primary database. The JDBC Thin driver (starting with Oracle Database

23ai) maintains physical connections to the primary database and True Cache. This model only works with Java applications.

The application switches between the primary database and True Cache without having to specify an instance name. The application uses special calls to flag the logical connection as read-only or read-write. If it's read-only, the query is sent to True Cache. Otherwise, it's sent to the primary database.

#### **Related Topics**

Using Oracle True Cache in Your Applications
 When True Cache is configured, applications must decide whether to query data from True Cache or the primary database.

### 1.6 Lock-Free Concurrency Control

For applications that work with JSON documents, Oracle extends HTTP entity tag (ETAG) support to implement lock-free, optimistic concurrency control.

A database GET request to True Cache automatically computes the ETAG and inserts it into the returned document. When the modified document is PUT back into the primary database, the following occurs:

- The database verifies that the underlying document rows still match the ETAG that was computed by the GET request.
- 2. If the rows match the ETAG, the rows are atomically updated.
- 3. If there's not a match, another user has changed the data and the PUT request is rejected.
- 4. The PUT request can be retried using the new data.

### **Configuring True Cache**

You can configure True Cache using the Oracle Database Configuration Assistant (Oracle DBCA) or you can configure it manually.

True Cache for Oracle Database Free has a simplified configuration process. Get started with the *Oracle Database Free Installation Guide* for your platform. See Configuring True Cache on Oracle Database Free (Linux) or Configuring True Cache on Oracle Database Free (Windows).

### 2.1 Overview of the True Cache Configuration

A True Cache environment can have a uniform or partitioned configuration.

### 2.1.1 Uniform Configuration

In a uniform configuration, you can deploy multiple, identical True Caches that use the same True Cache database application service.

Client sessions are evenly distributed among True Caches, which all cache the same set of data.

See the following technical architecture diagram for details and an example of a uniform configuration:

True Cache Uniform Configuration

### 2.1.2 Partitioned Configuration

In a partitioned configuration, the data is divided across multiple True Caches, which each cache a different subset of the data.

The total size of the cached data across all True Caches can be much larger than it would be for a single primary database or a single cache in a uniform configuration.

See the following technical architecture diagrams for details and examples of partitioned configurations:

- True Cache Configuration with colocation tag
- True Cache Partitioned Configuration with Multiple Services

### 2.1.3 True Cache Configuration Process Overview

At a high level, creating a True Cache configuration involves the following steps.

- Configure the network for True Cache and the primary database, and optionally create a remote listener for high availability.
- Create True Cache.
- Create and start the True Cache database application services.

### 2.1.4 Best Practices for Database Application Services

Associate each primary database application service with a corresponding True Cache database application service.

To distinguish the True Cache database application services, it's a good practice to use the primary service name followed by  $\, \, \mathbb{T} \mathbb{C}$ .

For example, if the primary service is SALES, the True Cache service would be SALES TC.

Also, only start the True Cache services on True Caches, and make sure they're read-only.

# 2.1.5 Best Practices for Maximum Availability Architecture (MAA) with True Cache

Follow these best practices for maximum availability with True Cache.

- Configure True Cache for high availability with two identical True Caches per dataset using the uniform configuration architecture. To learn more, see Uniform Configuration.
- Use the JDBC 23ai UCP connection configuration for the application to ensure minimal impact on the application if one True Cache becomes unavailable.
- Before enabling the database application service for True Cache, populate the cache by running critical workload queries. To learn more about how data is cached, see How True Cache Works.
- Before shutting down True Cache for planned maintenance, stop the database application service on True Cache.
- Partition or design True Caches to minimize fetches from the primary database.

### 2.1.6 Pluggable Database (PDB) Behavior and Restrictions with True Cache

To achieve maximum availability, PDBs on True Cache and the primary database have the following behavior and restrictions.

- Because non-CDB database are deprecated in Oracle 23ai, True Cache does not support non-CDB primary databases.
- You can't perform administration tasks (for example, opening, closing, or shutting down) on PDBs on True Cache. However, applications can connect to specific PDBs on True Cache the same way they do for primary databases and Oracle Active Data Guard.
- True Cache's PDB availability depends on the PDB state on the primary database.
  - When True Cache connects to the primary database, all open PDBs on the primary database (in any Oracle RAC instances) are open on True Cache.
  - If a PDB isn't open on the primary database on all Oracle RAC instances, then True Cache effectively can't read anything from that PDB and sees the PDB in a mounted state. When the primary database opens the PDB, then True Cache automatically opens it as well.

- When a PDB is closed on the primary database, it's marked as disconnected on True Cache and never closes, unless some other action on the primary database requires the PDB to close, like dropping it, renaming it, or using flashback. Otherwise, the PDB remains open forever. Even if the primary CDB shuts down, when the primary CDB restarts, True Cache checks whether each PDB can resume or has to be closed and restarted.
- When the primary database shuts down, ROOT is marked as disconnected on True Cache, and it may remain disconnected for a maximum of 24 hours.

The following example illustrates how a PDB can be open on one True Cache and closed on another True Cache that's connected to the same primary database.

- 1. PDB 1 is open on the primary database.
- 2. True Cache 1 connects to the primary database and sees that PDB 1 is open, so it opens PDB 1.
- 3. The primary database closes PDB 1, but PDB 1 stays open on True Cache 1.
- 4. The primary database is bounced but doesn't reopen PDB 1.
- 5. True Cache 2 connects to the primary database and sees PDB 1 is in a mounted state, so PDB 1 stays closed and mounted on True Cache 2.

### 2.2 Configuring True Cache with Oracle DBCA

The simplest way to configure a True Cache environment is to use Oracle Database Configuration Assistant (Oracle DBCA).

Oracle DBCA is an assistant tool that comes with Oracle Database to simplify the process of creating, configuring, and managing Oracle databases and True Caches.

True Cache for Oracle Database Free has a simplified configuration process. Get started with the *Oracle Database Free Installation Guide* for your platform. See Configuring True Cache on Oracle Database Free (Linux) or Configuring True Cache on Oracle Database Free (Windows).

### 2.2.1 Prerequisites

Before configuring True Cache, complete the following prerequisites.

- Set up a network path to access the primary (source) database with an Easy Connect (EZConnect) string from the True Cache node.
- Install the Oracle Database software on the True Cache nodes.
- Ensure that a primary database is running on the primary node in archive logging (ARCHIVELOG) mode.

The primary database must be in ARCHIVELOG mode to ship redo log files to the True Cache node. Oracle DBCA verifies that the primary database is in ARCHIVELOG mode.

If the primary database is not in ARCHIVELOG mode, restart it in mount mode, run the ALTER DATABASE ARCHIVELOG command, and open the primary database again.

- Don't set LOG\_ARCHIVE\_CONFIG and LOG\_ARCHIVE\_DEST\_n on the primary database. True Cache automatically configures these for the primary database.
- If LOG\_ARCHIVE\_DEST is set on the primary database, remove it. LOG\_ARCHIVE\_DEST is incompatible with the LOG\_ARCHIVE\_DEST\_n parameters. For more information, see LOG\_ARCHIVE\_DEST.

### 2.2.2 Creating True Cache with DBCA

Follow these steps to create True Cache with Oracle DBCA.

- Copy the password file, and optionally the Transparent Data Encryption (TDE) wallet, from the primary database to the True Cache node. You can use either of the following methods:
  - Manually copy the primary database's password file (and optional TDE wallet) to any location on the True Cache node.
  - Run a DBCA command on the primary database to package the password file (and optional TDE wallet) into a configuration BLOB file. Then copy the file to the True Cache node and ensure that the file is owned by the Oracle Home user.

Use the following command to prepare the configuration BLOB file on the primary database:

```
ORACLE_HOME/bin/dbca -configureDatabase -prepareTrueCacheConfigFile -sourceDB primary_db_sid_or_db_unique_name -trueCacheBlobLocation primary db config blob path -silent
```

#### Example:

```
$ORACLE_HOME/bin/dbca -configureDatabase -prepareTrueCacheConfigFile -
sourceDB primdbli -trueCacheBlobLocation /tmp/blob loc2 -silent
```

For descriptions of the parameters, see configureDatabase.

2. On the True Cache node, run the -createTrueCache command to complete the True Cache configuration and start True Cache.

Choose one of the following command formats, depending on the method that you used to copy the primary database's password file (and optional TDE wallet) to the True Cache node in step 1.

If you manually copied the password file (and optional TDE wallet), use this command:

```
ORACLE_HOME/bin/dbca -createTrueCache -gdbName true_cache_global_name -sid true_cache_sid -sourceDBConnectionString
primary_db_easy_connect_string -passwordFileFromSourceDB
password_file_path -sgaTargetInMB sga_memory_size -
pgaAggregateTargetInMB pga memory size -silent
```

#### Example using a password file:

\$ORACLE\_HOME/bin/dbca -createTrueCache -gdbName tcdb1 -sid tcdb1 sourceDBConnectionString primary.example.com:1522/primdb1i.example.com passwordFileFromSourceDB /tmp/password\_loc2/orapwddbmc1 -sgaTargetInMB
20000 -pgaAggregateTargetInMB 4000 -silent

If you created the configuration BLOB file, use this command:

```
ORACLE_HOME/bin/dbca -createTrueCache -gdbName true_cache_global_name -sid true_cache_sid -sourceDBConnectionString
primary_db_easy_connect_string -trueCacheBlobFromSourceDB
true_cache_config_blob_path -sgaTargetInMB sga_memory_size -
pgaAggregateTargetInMB pga_memory_size -tdeWalletLoginType AUTO_LOGIN -
listeners listener name -silent
```

#### Example using a TDE wallet:

\$ORACLE\_HOME/bin/dbca -createTrueCache -gdbName tcdb1 -sid tcdb1 sourceDBConnectionString primary.example.com:1522/primdb1i.example.com trueCacheBlobFromSourceDB /tmp/blob\_loc2/blob.tar.gz -sgaTargetInMB
20000 -pgaAggregateTargetInMB 4000 -tdeWalletLoginType AUTO\_LOGIN listeners LISTENER -silent

For descriptions of the parameters, see createTrueCache.

For Oracle RAC primary databases, set the -sourceDBConnectionString parameter to SCAN:port/service\_name.

#### **Related Topics**

Rerunning Oracle DBCA After Creating True Cache
 If you need to rerun Oracle DBCA after creating True Cache, clean up the True Cache node first.

### 2.2.3 Configuring True Cache Database Application Services with DBCA

To use True Cache with the JDBC Thin driver, for each primary database application service that you want to cache, create a corresponding True Cache database application service.

This makes it easy for applications to switch an existing JDBC connection from a primary database to True Cache without having to change the JDBC connection URL. This is possible with the 23ai JDBC Thin driver by setting the <code>ReadOnly</code> parameter of the connection to <code>TRUE</code> or <code>FALSE</code>.

On the primary database, complete the following steps:

Configure the remote listener.

Check to see if Valid Node Checking for Registration (VNCR) is configured for the listener. If so, add True Cache to the

REGISTRATION\_INVITED\_NODES\_LISTENER parameter in the listener.ora file of the remote listener.

#### Note:

For Oracle RAC primary databases, add the True Cache node to the invited node list for the SCAN listener by using the srvctl command line utility. (Don't manually edit the listener.ora file as the grid owner user.)

For example:

```
srvctl modify scan_listener -invitednodes true_cache_host -
endpoints TCP:port
```

2. Create and start a primary database application service to use with the True Cache service, and then verify that the service is running.

Choose one of the following options based on the primary database configuration:

 For single instance primary databases, use the DBMS\_SERVICE PL/SQL package. For services that are specific to a pluggable database (PDB), connect to the specific PDB, or set the correct PDB container in your session before starting the service using DBMS\_SERVICE.

Here's an example using the <code>DBMS\_SERVICE</code> package for a single instance primary database:

 For Oracle RAC primary databases, use the srvctl command line utility to add the primary database service. Start the service on the primary instance. Use srvctl only for Oracle Clusterware-managed instances.

```
srvctl add service -db primary_db_unique_name -service
primary_db_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name

srvctl start service -d primary_db_unique_name -s
primary_db_service_name
```

#### For example:

```
srvctl add service -db primdb1i -service sales -preferred
primdb1i1,primdb1i2 -pdb sales_pdb
srvctl start service -d primdb1i -s sales
```

3. Run the dbca -configureDatabase command with the - configureTrueCacheInstanceService parameter to configure True Cache.

This configures the True Cache database application service on the primary database and then starts the True Cache service on True Cache. Run this command for each True Cache database application service.

The primary database application service must already exist before you run this command.

#### Note:

For a uniform True Cache configuration with multiple True Caches serving the same service, DBCA starts the service on the first True Cache and then you manually start the service on the other True Caches.

```
ORACLE_HOME/bin/dbca -configureDatabase -configureTrueCacheInstanceService -sourceDB primary_db_sid_or_db_unique_name -trueCacheConnectString true_cache_easy_connect_string -trueCacheServiceName true_cache_service_name -serviceName primary_db_service_name -pdbName primary pdb name -silent
```

#### Example:

```
$ORACLE_HOME/bin/dbca -configureDatabase -
configureTrueCacheInstanceService -sourceDB primdb1i -
trueCacheConnectString tc.example.com:1522/tcdb1.example.com -
trueCacheServiceName sales tc -serviceName sales -pdbName sales pdb -silent
```

For descriptions of the parameters, see configureDatabase.

4. After the database application service starts on True Cache, use the lsnrctl command to validate the remote listener services for the True Cache service registration.

See Verifying the Remote Listener Configuration.

**5.** For a uniform True Cache configuration with multiple True Caches serving the same service, start the service on all additional True Caches. For example:

```
EXEC DBMS SERVICE.START SERVICE('SALES TC');
```

#### **Related Topics**

- CREATE SERVICE Procedure
- MODIFY\_SERVICE Procedure
- srvctl modify scan\_listener
- Uniform Configuration

In a uniform configuration, you can deploy multiple, identical True Caches that use the same True Cache database application service.

Rerunning Oracle DBCA After Configuring True Cache Database Application Services
If you need to rerun Oracle DBCA after configuring True Cache database application
services, you might need to delete the True Cache service from the primary pluggable
database (PDB) using the DBMS\_Service package.

### 2.2.4 Oracle DBCA Commands and Parameters for True Cache

Use the following Oracle DBCA commands and parameters to configure True Cache.

### 2.2.4.1 configure Database

The configureDatabase command configures the primary database for True Cache. Run this command on the primary database.

#### **Parameters**

For True Cache, use the dbca -configureDatabase command with the following syntax.

This table lists the <code>configureDatabase</code> parameters that are specific to True Cache. For the full syntax and parameters, see configureDatabase in the *Oracle Multitenant Administrator's Guide*.

Table 2-1 configureDatabase Parameters

Parameter	Required/ Optional	Description
prepareTrueCacheConfigFile	Required for True Cache	Use this option to prepare a configuration BLOB file that contains the primary database's password file or wallet.  Enter the following additional parameters for this option:  -sourceDB: Enter the primary database system identifier (SID) or database unique name (DB_UNIQUE_NAME).  -tdeWalletPassword: If the primary database uses a Transparent Data Encryption (TDE) wallet, enter the password for the wallet. This parameter is optional.  -trueCacheBlobLocation: Enter the path where you want to save the configuration BLOB file on the primary database. This parameter is optional.

Table 2-1 (Cont.) configureDatabase Parameters

Parameter	Required/ Optional	Description
- configureTrueCacheInstanceServ ice	Required for True Cache	Use this option to configure the True Cache database application service on the primary database and start the service on True Cache.
		Enter the following additional parameters for this option:
		-serviceName: Enter the primary database application
		service name.
		<ul> <li>-sourceDB: For a single instance database, enter the primary database SID. For an Oracle RAC database, enter the database unique name (DB_UNIQUE_NAME).</li> </ul>
		<ul> <li>-trueCacheConnectString: Enter the Easy Connect (EZConnect) string to connect to True Cache.</li> </ul>
		<pre>Example: host:port/service_name</pre>
		<ul> <li>-trueCacheServiceName: Enter a name for the True</li> <li>Cache database application service.</li> </ul>
		<ul> <li>pdbName: Enter the primary pluggable database (PDB) name. This parameter is required to create the True Cache service for a PDB. In this case serviceName is an existing PDB service name in the primary database.</li> </ul>
- cleanupTrueCacheInstanceServic e	Required for True Cache	Use this option to remove the True Cache database application services from the primary database configuration if, for example, you delete True Cache.
		Enter the following additional parameters for this option:
		-serviceName: Enter the primary database application
		service name.
		<ul> <li>-sourceDB: Enter the primary database SID or database unique name (DB_UNIQUE_NAME).</li> </ul>
		<ul> <li>-trueCacheConnectString: Enter the Easy Connect (EZConnect) string to connect to True Cache.</li> </ul>
		Example: host:port/service name
		-trueCacheServiceName: Enter a name for the True     Cache database application service.

#### 2.2.4.2 createTrueCache

The createTrueCache command configures True Cache. Run this command on the True Cache node.

#### **Syntax and Parameters**

Use the dbca -createTrueCache command with the following syntax:

```
dbca -createTrueCache
  -dbUniqueName true_cache_unique_name | -gdbName true_cache_global_name
  -sourceDBConnectionString primary_db_easy_connect_string
  -trueCacheBlobFromSourceDB true_cache_config_blob_path | -
passwordFileFromSourceDB password_file_path
      [-tdeWalletFromSourceDB tde_wallet_path]
      [-createListener new_database_listener]
```

```
[-datafileDestination true_cache_control_file_path
[-initParams initialization_parameters_list
        [-initParamsEscapeChar initialization_parameters_escape_character]]
[-listeners listener_list]
[-pgaAggregateTargetInMB pga_memory_size]
[-sgaTargetInMB sga_memory_size]
[-sid true_cache_sid]
[-sourceTdeWalletPassword primary_db_wallet_password]
[-tdeWalletLoginType {PASSWORD | AUTO_LOGIN | LOCAL_AUTO_LOGIN}]
[-tdeWalletRoot tde_wallet_root_init_parameter]
[-useWalletForDBCredentials {true | false}
        -dbCredentialsWalletPassword wallet_account_password]]
```

Table 2-2 createTrueCache Parameters

Parameter	Required/ Optional	Description
-dbUniqueName	Required	Enter either the unique name for this True Cache or the global
true_cache_unique_name		database name.
or		
-gdbName		
true_cache_global_name		
-sourceDBConnectionString primary db easy connect string	Required	Enter the Easy Connect (EZConnect) string to connect to the primary database.
primary_us_eusy_commess_sering		<pre>Example: host:port/service_name</pre>
		<b>Note:</b> For Oracle RAC primary databases, set the - sourceDBConnectionString parameter to SCAN:port/service_name.
-trueCacheBlobFromSourceDB	Required	Enter one of the following:
<pre>true_cache_config_blob_path or -passwordFileFromSourceDB</pre>		<ul> <li>The full path and file name for the configuration BLOB file that contains the primary database's password file or wallet. This is the path where the file is located on the True Cache node.</li> </ul>
password_file_path		<ul> <li>The path to the primary database's password file that was copied to the True Cache node.</li> </ul>
		If you use -passwordFileFromSourceDB, you can also enter the following additional parameter:
		-tdeWalletFromSourceDB: Enter the path to the primary database's Transparent Data Encryption (TDE) wallet file that was copied to the True Cache node. You can copy and use the TDE wallet file only if the primary (source) database has TDE enabled. Otherwise, the wallet file isn't required.
-createListener	Optional	Enter a new database listener to be created and to register the
new_database_listener		database in the form LISTENER_NAME:PORT.

Table 2-2 (Cont.) createTrueCache Parameters

Parameter	Required/ Optional	Description
-datafileDestination	Optional	Enter the location where the True Cache control file, standby
true cache control file path		redo log groups, and temporary data files are to be stored.
crac_oao.ic_oo.icroi_irio_pac.i		If True Cache uses Oracle Automatic Storage Management (ASM) storage or Oracle Exadata Exascale Storage Vault, prefix the path with the ASM disk group or Exascale Vault namfor -datafileDestination and use the following additional parameter:
		-useOMF: Enter true to use Oracle-Managed Files (OMF).
		Otherwise, enter false.

Make sure the directory has enough space to hold the temporary files in the primary database plus four times the maximum online redo log size per block size and per thread. For example, if the primary has two redo log threads and each thread has two 2GB online redo logs with 512-byte blocks, two 4GB online redo logs with 512-byte blocks, and three 8GB online redo logs with 4KB blocks, use the following formula: 2 threads x ((4GB x 2, for the biggest of the 512-byte blocks) + (8KB x 3, for the 4KB blocks)).

<pre>-initParams initialization_parameters_list</pre>	Optional	Enter a comma-separated list of name=value pairs with additional initialization parameter values for this True Cache. You can also provide the -initParamsEscapeChar parameter for using a specific escape character between multiple values of an initialization parameter. If an escape character is not specified, backslash (\) is used as the default escape character.
-listeners	Optional	If one or more listeners already exist, enter a comma-separated
listeners_list		list of existing listeners that the database can be configured with. If you don't specify the existing listeners, DBCA creates a new listener.
-pgaAggregateTargetInMB	Optional	Enter a value in MB for the target aggregate Program Global
pga_memory_size		Area (PGA) memory to make available to all server processes that are attached to this True Cache.
-sgaTargetInMB	Optional	Enter a value in MB for the System Global Area (SGA) memory
sga_memory_size		size for this True Cache.
-sid	Optional	Enter the system identifier (SID) for this True Cache.
true_cache_sid		

Table 2-2 (Cont.) createTrueCache Parameters

Parameter	Required/ Optional	Description
-sourceTdeWalletPassword primary_db_wallet_password	Optional	If the primary database uses a TDE wallet, enter the password for the wallet.
-tdeWalletLoginType {PASSWORD   AUTO_LOGIN   LOCAL AUTO LOGIN}	Optional	Oracle recommends the AUTO_LOGIN or LOCAL_AUTO_LOGIN wallet for True Cache to avoid having to manually open a password wallet for each True Cache startup.
		To learn more about wallet types, see About Oracle Database Wallets
<pre>-tdeWalletRoot tde_wallet_root_init_parameter</pre>	Optional	Enter the location for the True Cache TDE wallet root initialization parameter, which specifies where to place the wallet for True Cache.
<pre>-useWalletForDBCredentials {true   false}</pre>	Optional	If the primary database uses Oracle Wallet for database credentials, enter true. The default is false.
(3230 ) 23200,		If you enter true, also enter the following additional parameters:
		<ul> <li>-dbCredentialsWalletLocation: Enter the path of the directory that contains the Oracle Wallet files.</li> </ul>
		<ul> <li>-dbCredentialsWalletPassword: Enter the password for the Oracle Wallet account to open the wallet with auto- login disabled. This parameter is optional.</li> </ul>

#### **Related Topics**

createTrueCache

### 2.3 Configuring True Cache Manually

Follow these steps to set up a True Cache environment manually if you're not using the Oracle Database Configuration Assistant (Oracle DBCA).

### 2.3.1 Prerequisites

Before configuring True Cache, complete the following steps.

- Install the Oracle Database software on the True Cache nodes.
- Ensure that a primary database is running on the primary node in archive logging (ARCHIVELOG) mode.

The primary database must be in ARCHIVELOG mode to ship redo log files to the True Cache node. To see if the primary database is in ARCHIVELOG mode, enter the following SQL query:

SELECT log\_mode FROM v\$database;

LOG\_MODE
-----ARCHIVELOG

If the primary database is not in ARCHIVELOG mode, restart it in mount mode, run the ALTER DATABASE ARCHIVELOG command, and open the primary database again.

- Don't set LOG\_ARCHIVE\_CONFIG and LOG\_ARCHIVE\_DEST\_n on the primary database. True Cache automatically configures these for the primary database.
- If LOG\_ARCHIVE\_DEST is set on the primary database, remove it. LOG\_ARCHIVE\_DEST is incompatible with the LOG\_ARCHIVE\_DEST\_n parameters. For more information, see LOG\_ARCHIVE\_DEST.

### 2.3.2 Creating True Cache Manually

Follow these steps to create True Cache manually.

### 2.3.2.1 Edit the thsnames.ora File for True Cache and the Primary Database

Configure the database network connections by editing the tnsnames.ora file on both True Cache and the primary database.

On most Linux platforms, you find the tnsnames.ora file in the <code>\$ORACLE\_HOME/network/admin</code> directory.

You can create this file manually or by using Oracle Net Configuration Assistant (NETCA).

Add the following information to all primary database and True Cache tnsnames.ora files if the information isn't already present:

- Network names for the primary database and all True Caches. These are needed to send redo to True Cache, and they enable redo shipping to work even if the database application services are not yet created.
- All primary database and True Cache database application service names. One True Cache can support multiple database application services that are started simultaneously.
- All participating listener network aliases, if you're using a remote listener.

Here are examples of the entries in the tnsnames.ora files for True Cache and the primary database:

```
(CONNECT DATA =
      (SERVICE NAME = sales tc)
    )
# Primary database network name
primdbli =
  (DESCRIPTION =
    (ADDRESS LIST =
      (ADDRESS = (PROTOCOL = TCP) (HOST = primary_database_host) (PORT = 1521))
    (CONNECT DATA =
     (SID = primdb1i)
# Primary database application service name
sales =
  (DESCRIPTION =
    (ADDRESS LIST =
      (ADDRESS = (PROTOCOL = TCP) (HOST = primary database host) (PORT = 1521))
    (CONNECT DATA =
      (SERVICE NAME = sales)
listener primary =
  (DESCRIPTION =
    (ADDRESS = (PROTOCOL = TCP) (HOST = primary database host) (PORT=1521))
listener true cache =
  (DESCRIPTION =
    (ADDRESS = (PROTOCOL = TCP) (HOST = true cache host) (PORT=1521))
```

### 2.3.2.2 Configure and Start the Local Listener on the True Cache Node

Configure and start the local listener to enable the True Cache node to receive redo from the primary database.

1. Create the listener.ora file manually or by using NETCA.

Here's an example of listener.ora on a True Cache node:

```
SID_LIST_LISTENER =
  (SID_LIST =
   (SID_DESC =
```

```
(GLOBAL_DBNAME = tcdbli)
  (ORACLE_HOME = local_oracle_home_on_true_cache)
  (SID_NAME = tcdbli)
)

LISTENER =
  (DESCRIPTION =
        (ADDRESS = (PROTOCOL = TCP) (HOST = true_cache_host) (PORT = 1521))
)
```

2. In a command window, ensure that the <code>ORACLE\_HOME</code> and <code>ORACLE\_SID</code> environment variables are set properly.

See Configuring the Operating System Environment Variables.

- 3. Ensure that the \$ORACLE HOME/bin directory is in your PATH environment variable.
- 4. Start the listener and verify that it started correctly.

```
lsnrctl start
lsnrctl status
```

## 2.3.2.3 Copy the Password File or Wallet from the Primary Database to the True Cache Node

To provide authentication for redo transport sessions, copy the primary database's password file or wallet to the True Cache node.

True Cache uses Oracle Net to transport redo data and control messages between the members of a True Cache configuration. These redo transport sessions are authenticated using a password file, so every True Cache in the configuration needs an up-to-date copy of the password file from the primary database.

Copy the primary database's password file to the appropriate directory on the True Cache node. You can find the password file in the V\$PASSWORDFILE\_INFO view, and on Linux the file is usually in \$ORACLE HOME/dbs/orapwSID.

In the examples in this documentation, the primary database's password file is <code>\$ORACLE\_HOME/dbs/orapwprimdbli</code> and would be copied to a True Cache node and renamed to <code>\$ORACLE\_HOME/dbs/orapwtcdbli</code>.

You need to recopy the password file in the following situations:

- Whenever an administrative privilege (SYSDG, SYSOPER, SYSDBA, and so on) is granted or revoked.
- After the password of any user with administrative privileges is changed.

Copy the wallet instead of the password file in the following situations:

- If the primary database uses TLS certificate authentication instead of a password file.
- If the primary database configures Transparent Data Encryption (TDE). Include only the ROOT container's master key in the copy for True Cache, which is used to decrypt encrypted redo that's shipped from the primary database.

#### Note:

When using a TDE wallet, Oracle recommends configuring an auto-login or local auto-login wallet for True Cache. For auto-login wallets, you an create the wallet on the primary database and copy both the password wallet (ewallet.p12) and auto-login wallet (cwallet.sso) to True Cache. Local auto-login wallets are host-specific, so you can't copy them to another node. Instead, for local auto-login wallets, copy the password wallet to True Cache, open it on True Cache, and create the local auto-login wallet there with the wallet password. The local auto-login wallet offers more security because it prevents someone from copying both wallets and using them without knowing the wallet password. To learn more about wallet types, see About Oracle Database Wallets. To learn more about wallet types, see About Oracle Database Wallets

### 2.3.2.4 Prepare a PFILE for True Cache

For each True Cache, prepare a PFILE with the following parameters.

Table 2-3 Initialization Parameters

Parameter	Description
TRUE_CACHE=TRUE	This tells the server that this is a True Cache.
DB_NAME	Enter the same value as the one for the primary database.
DB_UNIQUE_NAME	Specify a unique name for this True Cache.
DB_FILES	Enter the same value as the one for the primary database.
SGA_TARGET	Enter the SGA memory size of this True Cache.

Table 2-3 (Cont.) Initialization Parameters

#### **Parameter**

#### REMOTE LISTENER

#### Description

Enter the primary database listener. This is not needed for the CREATE TRUE CACHE command, but it's needed to use JDBC.

**Note:** For Oracle RAC primary databases, set the REMOTE LISTENER parameter to SCAN:port.

Note: Check to see if Valid Node Checking for Registration (VNCR) is configured for the listener. If so, add True Cache to the REGISTRATION\_INVITED\_NODES\_LISTENER parameter in the listener.ora file of the remote listener. (In the example following this table,

this is the primary database's listener.ora file.)

Note: To simplify configuration and avoid connection issues, you can use the LISTENER\_NETWORKS parameter instead of specifying REMOTE\_LISTENER and LOCAL\_LISTENER separately. All listeners within the same network\_name will cross-register. For example:

LISTENER\_NETWORKS='((NAME=network\_name)
(LOCAL\_LISTENER=(DESCRIPTION=(ADDRESS=(PROTOCOL=TCP)(HOST=true\_cache\_host)(PORT=1521))))
(REMOTE\_LISTENER=primary\_database\_host:1521))'

For more information, see Best Practices for Load Balancing in a Uniform Configuration.

Enter the network name for the primary database.

**Note:** For Oracle RAC primary databases, set the FAL\_SERVER parameter to SCAN:port/service name.

If you have standby databases that could become a primary after a primary-standby switchover, True Cache automatically adds the existing standby databases to the FAL\_SERVER list. However, if you add a new standby database after configuring True Cache, you need to append the new standby database to the FAL\_SERVER parameter for True Cache. To do this, use the following command with a comma-separated list of databases:

ALTER SYSTEM SET

FAL\_SERVER='existing\_databases,new\_st
andby database' SCOPE=BOTH

FAL SERVER

Table 2-3 (Cont.) Initialization Parameters

Parameter	Description
FAL_CLIENT	Enter the True Cache network name. When you start True Cache, it automatically adds that network name to the corresponding primary database LOG_ARCHIVE_DEST_n initialization parameter so that the primary database knows where to send online redo log blocks.
DB_CREATE_FILE_DEST	Enter a directory to store the internal True Cache files (for example, control files and temp files).
	If True Cache uses Oracle Automatic Storage Management (ASM) storage or Oracle Exadata Exascale Storage Vault, prefix the path with the ASM disk group or Exascale Vault name.

Make sure the directory has enough space to hold the temporary files in the primary database plus four times the maximum online redo log size per block size and per thread. For example, if the primary has two redo log threads and each thread has two 2GB online redo logs with 512-byte blocks, two 4GB online redo logs with 512-byte blocks, and three 8GB online redo logs with 4KB blocks, use the following formula: 2 threads x ((4GB x 2, for the biggest of the 512-byte blocks) + (8KB x 3, for the 4KB blocks)).

ary if the primary database Set this to the domain where resides.
e configures TDE with the  T_ROOT and  parameters, configure them  ue Cache.

For example, the following PFILE is named init\_tcdb1i.ora and stored in the \$ORACLE HOME/dbs/ directory on the True Cache node:

```
true_cache=true
db_name=primaryd
db_unique_name=tcdb1
db_files=200
sga_target=20G
fal_server=primdb1i
fal_client=tcdb1i
instance_name=tcdb1i
db_create_file_dest=local_directory_on_true_cache_node
local_listener=listener
remote_listener=listener_primary
```

The preceding example assumes that the primary database's <code>DB\_UNIQUE\_NAME</code> initialization parameter is set to <code>primarydb</code> and <code>DB\_FILES</code> is set to <code>200</code>.

#### **Related Topics**

- TRUE CACHE
- Initialization Parameters

#### 2.3.2.5 Create and Start True Cache

Follow these steps to create and start True Cache for the first time.

1. Start up True Cache in NOMOUNT mode using SQL\*Plus.

```
export ORACLE_SID=tcdb1i
sqlplus / as SYSDBA
STARTUP NOMOUNT PFILE=$ORACLE HOME/dbs/init tcdb1i.ora;
```

2. Verify that the password file points to the right file.

Create and start True Cache.

```
CREATE TRUE CACHE;
```

4. To verify that True Cache is working, see Verifying That True Cache Is Working as Expected.

When you create True Cache, it automatically creates standby redo logs with the appropriate size, control files, temp files (when needed), and an internal SPFILE based on the first PFILE

that you created. This SPFILE is used automatically on later STARTUP commands without the need to specify any PFILE values.

At this point, your applications can use separate physical connections to the primary database and True Cache and choose which connection to use based on whether it's reading or writing.

To use True Cache with the JDBC Thin driver, continue to the next topic to configure the database application services for True Cache.

### 2.3.3 Configuring True Cache Database Application Services Manually

To use True Cache with the JDBC Thin driver, for each primary database application service that you want to cache, create a corresponding True Cache database application service.

This makes it easy for applications to switch an existing JDBC connection from a primary database to True Cache without having to change the JDBC connection URL. This is possible with the 23ai JDBC Thin driver by setting the ReadOnly parameter of the connection to TRUE or FALSE.

### 2.3.3.1 Create Database Application Services on the Primary Database

You can associate one primary database service with one True Cache service.

From the primary database, create or modify the True Cache and primary database services using one of the following methods.

#### **True Cache and Single Instance Primary Databases**

For True Cache and single instance primary databases, use the <code>DBMS\_SERVICE</code> PL/SQL package. For services that are specific to a pluggable database (PDB), connect to the specific PDB, or set the correct PDB container in your session before starting the service using <code>DBMS\_SERVICE</code>.

Here's an example of creating these two services using the <code>DBMS\_SERVICE</code> package for a single instance primary database:

```
DECLARE
    db params dbms service.svc parameter array;
BEGIN
  -- create a database application service for True Cache called SALES TC
using SALES TC tnsname
  DBMS SERVICE.CREATE SERVICE('SALES TC', 'SALES TC', db params);
  -- create a database application service SALES for primary database using
SALES thsname and associate it to the SALES TC service name using
TRUE CACHE SERVICE attribute
   db_params('true_cache_service') := 'SALES_TC';
  DBMS SERVICE.CREATE SERVICE('SALES', 'SALES', db params);
   -- or, modify an already existing primary database application service
called SALES to associate it to the SALES TC service name using the
TRUE CACHE SERVICE attribute
  db params('true cache service') := 'SALES TC';
  DBMS SERVICE.MODIFY SERVICE('SALES', db params);
END;
```

#### **Oracle RAC Primary Databases**

For Oracle RAC primary databases, use the <code>srvctl</code> command line utility to add the services. Start the service on the primary instance. Use <code>srvctl</code> only for Oracle Clusterware-managed instances.

To create both a True Cache service and the primary database service:

```
srvctl add service -db primary_db_unique_name -service
true_cache_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name
```

```
srvctl add service -db primary_db_unique_name -service
primary_db_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name -true_cache_service true_cache_service_name
```

#### For example:

```
srvctl add service -db primdbli -service sales_tc -preferred
primdbli1,primdbli2 -pdb sales_pdb
srvctl add service -db primdbli -service sales -preferred primdbli1,primdbli2
-pdb sales_pdb -true_cache_service sales_tc
```

To create a True Cache service for an existing primary database service (db service name):

```
srvctl add service -db primary_db_unique_name -service
true_cache_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name
```

```
srvctl modify service -db primary_db_unique_name -service
primary db service name -true cache service true cache service name
```

#### For example:

```
srvctl add service -db primdb1i -service sales_tc -preferred
primdb1i1,primdb1i2 -pdb sales_pdb
srvctl modify service -db primdb1i -service sales -true cache service sales tc
```

#### Note:

Also disable the True Cache service on the cluster where it was added to prevent errors when stopping and restarting the primary database services. For example:

```
srvctl start service -d primdbli -s sales_tc
srvctl stop service -d primdbli -s sales_tc
srvctl disable service -d primdbli -s sales_tc
```

This doesn't affect standby databases or True Caches because they run outside the cluster where the True Cache service is disabled. The disabled status is not stored in the primary dictionary and <code>DBA\_SERVICES</code>, but only in Cluster Ready Services (CRS), and only in the cluster where the True Cache service was added. Other databases outside the cluster can start the service with <code>DBMS\_SERVICE.START\_SERVICE</code> and aren't affected by this setting.

### 2.3.3.2 Verify That the Database Application Services Are Created

After you create services on the primary database, True Cache automatically inherits their definitions. Using SQL\*Plus, make sure that you can see the same results on both the primary database and True Cache.

#### For example:

### 2.3.3.3 Start the Database Application Services

Using SQL\*Plus, start the database application services on both the primary database and True Cache.

#### Example 2-1 True Cache

```
connect / as SYSDBA

SELECT database_role FROM v$database;

DATABASE_ROLE
______
TRUE CACHE

EXEC DBMS_SERVICE.START_SERVICE('SALES_TC');

SELECT service_id, name FROM v$active_services WHERE name='SALES_TC';

SERVICE_ID NAME
______
28 SALES TC
```

#### **Example 2-2 Primary Database**

#### **Related Topics**

- Verify That the Database Application Services Are Created
   After you create services on the primary database, True Cache automatically inherits their
   definitions. Using SQL\*Plus, make sure that you can see the same results on both the
   primary database and True Cache.

### 2.4 Deploying True Cache for an Oracle RAC Primary Database

This section summarizes the configuration requirements for deploying True Cache for a primary database in an Oracle Real Application Clusters (Oracle RAC) environment. These requirements are also included in context within the detailed configuration steps.

All of this information also appears in the context of the configuration steps for Configuring True Cache with Oracle DBCA and Configuring True Cache Manually.

- True Cache needs to be able to access each instance in the Oracle RAC environment. To
  do this, use the single client access name (SCAN) listener when configuring True Cache.
  - If you're configuring True Cache with DBCA, set the -sourceDBConnectionString parameter to SCAN:port/service name.
  - If you're manually configuring True Cache, use the following settings when preparing the PFILE for True Cache:
    - \* Set the REMOTE LISTENER parameter to SCAN: port.
    - \* Set the FAL SERVER parameter to SCAN:port/service name.
  - Add the True Cache node to the invited node list for the SCAN listener by using the srvctl command line utility. (Don't manually edit the listener.ora file as the grid owner user.)

#### For example:

```
srvctl modify scan_listener -invited
nodes true\_cache\_host -endpoints TCP: port
```

 When creating the database application services on the primary database, use the srvctl command line utility to add the services. Start the service on the primary instance. Use srvctl only for Oracle Clusterware-managed instances.

To create both a True Cache service and the primary database service:

```
srvctl add service -db primary_db_unique_name -service
true_cache_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name
```

```
srvctl add service -db primary_db_unique_name -service
primary_db_service_name -preferred primary_db_instance_list -pdb
primary_pdb_name -true_cache_service true_cache_service_name
```

#### For example:

```
srvctl add service -db primdbli -service sales_tc -preferred
primdbli1,primdbli2 -pdb sales_pdb
srvctl add service -db primdbli -service sales -preferred
primdbli1,primdbli2 -pdb sales pdb -true cache service sales tc
```

### To create a True Cache service for an existing primary database service (db service name):

```
srvctl add service -db primary_db_unique_name -service
true_cache_service_name -preferred primary_db_instance_list -pdb
primary pdb name
```

```
srvctl modify service -db primary_db_unique_name -service
primary db service name -true cache service true cache service name
```

#### For example:

```
srvctl add service -db primdb1i -service sales_tc -preferred
primdb1i1,primdb1i2 -pdb sales_pdb
srvctl modify service -db primdb1i -service sales -true_cache_service
sales tc
```

#### Note:

Also disable the True Cache service on the cluster where it was added to prevent errors when stopping and restarting the primary database services. For example:

```
srvctl start service -d primdbli -s sales_tc
srvctl stop service -d primdbli -s sales_tc
srvctl disable service -d primdbli -s sales tc
```

This doesn't affect standby databases or True Caches because they run outside the cluster where the True Cache service is disabled. The disabled status is not stored in the primary dictionary and DBA\_SERVICES, but only in Cluster Ready Services (CRS), and only in the cluster where the True Cache service was added. Other databases outside the cluster can start the service with DBMS SERVICE.START SERVICE and aren't affected by this setting.

#### **Related Topics**

srvctl modify scan\_listener

### 2.5 Verifying the True Cache Configuration

Verify that True Cache and the database application services are working as expected.

### 2.5.1 Verifying That True Cache Is Working as Expected

To verify that True Cache is applying redo and making progress, check the following queries on True Cache.

1. Run SQL\*Plus on the True Cache.

```
sqlplus / as SYSDBA
```

2. Enter the following query:

```
SELECT database role, open mode FROM v$database;
```

The output should look like this:

```
DATABASE_ROLE OPEN_MODE
TRUE CACHE READ ONLY WITH APPLY
```

If OPEN\_MODE is READ ONLY WITH APPLY, it means that the True Cache redo apply is actively working.

3. Enter the following query multiple times:

```
SELECT current scn FROM v$database;
```

If CURRENT\_SCN is advancing over time, it means that True Cache is moving forward as expected.

4. To find the size of each log file, enter the following query:

```
SELECT THREAD#, SEQUENCE#, BYTES FROM v$standby log;
```

### 2.5.2 Verifying the Remote Listener Configuration

After the database application service starts on True Cache, use the lsnrctl command to validate the remote listener services for the True Cache service registration.

For Oracle RAC primary databases, before using the <code>lsnrctl</code> command, set your <code>\$ORACLE\_HOME</code> environment variable to the path for the Oracle Grid Infrastructure home (Grid home).

The following example shows two True Caches registered with the SCAN listener for an Oracle RAC primary database:

```
lsnrctl services LISTENER_SCAN1
Service "sales tc" has 2 instance(s).
```

### Note:

If the True Cache service is not registered with the remote listener, validate the remote listener invited nodes and the True Cache initialization parameters for REMOTE LISTENER OF LISTENER NETWORKS.

### 2.5.3 Verifying the True Cache and Primary Database Application Services

Verify that all database application services are active on both the primary database and True Cache.

#### **True Cache**

1. Run SQL\*Plus on True Cache.

```
sqlplus / as SYSDBA
```

2. Enter the following query:

```
SELECT service_id, name FROM v$active_services WHERE
name='true_cache_service_name';
```

### For example:

### **Primary Database**

Run SQL\*Plus on the primary database.

```
sqlplus / as SYSDBA
```

#### Enter the following query:

```
SELECT service_id, name, true_cache_service FROM v$active_services WHERE name='primary_db_service_name';
```

#### For example:

#### **Related Topics**

- Configuring True Cache Database Application Services Manually
   To use True Cache with the JDBC Thin driver, for each primary database application
   service that you want to cache, create a corresponding True Cache database application
- V\$ACTIVE SERVICES

### 2.6 Enabling DML Redirection

service.

True Cache is a read-only cache, so you can't directly update the cache, but you can use DML redirection to indirectly update the cache.

DML redirection writes data to the primary database and then that data is automatically updated in the cache. This is similar to how Oracle Active Data Guard works. Because DML redirection uses more resources, it's not recommended for update-intensive applications.

To enable and use DML redirection, set the <code>ADG\_REDIRECT\_DML</code> initialization parameter to <code>TRUE</code> on True Cache.

### Note:

If the user logs in to True Cache with OS authentication, the user can't enable <code>ADG\_REDIRECT\_DML</code>. This is because the True Cache database administrator might not actually have the <code>SYSDBA</code> password but is allowed to use OS authentication to manage True Cache as <code>SYSDBA</code>. If the user can set <code>ADG\_REDIRECT\_DML</code>, then that user can update primary data as <code>SYSDBA</code> without knowing the <code>SYSDBA</code> password.

For more on enabling DML redirection, see Managing Physical and Snapshot Standby Databases.

# Deploying True Cache in Containers

Containers can simplify the deployment of True Cache configurations.

You can use the scripts that are provided in the True Cache container image to automatically create a True Cache configuration. The scripts complete the following configuration tasks:

- Create the primary database and True Cache containers.
- Create and start True Cache.
- Create and start the database application services for the primary database and True Cache.

See the complete instructions for downloading the images and creating the containers in the Oracle Database Container Images README.md.

Create a separate container for each True Cache. Assign different container names, Oracle SIDs, and database application service names, as needed.

4

# Shutting Down and Starting True Cache

You can shut down and start an existing True Cache.

Perform these tasks on the True Cache container database (CDB), not on the pluggable database (PDB).

### 4.1 Shutting Down True Cache

To shut down True Cache, use the SHUTDOWN command.

Before shutting down True Cache for planned maintenance, stop the database application service on True Cache.

```
connect / as SYSDBA;
SHUTDOWN;
```

When you shut down True Cache, the cached content is lost. When you restart True Cache, it fetches the content again from the primary database.

### 4.2 Starting True Cache

To start an existing True Cache, use the STARTUP command.

```
connect / as SYSDBA;
STARTUP;
```

Work is automatically routed to True Cache when it declares that it's ready to support the True Cache service.

# Monitoring True Cache

You can monitor True Cache with the V\$TRUE\_CACHE view, and you can use the Automatic Workload Repository (AWR) to gather performance statistics for True Cache.

## 5.1 Monitoring True Cache with the V\$TRUE\_CACHE View

Use the  $V\$TRUE\_CACHE$  view to monitor the overall relationship and health of a True Cache configuration.

You can query the V\$TRUE\_CACHE view on the primary database and True Cache. On True Cache, the view displays a single row for the primary database that it connects to. On the primary database, the view shows one row for each True Cache that's connected to the primary database. Each row displays the status for the True Cache.

To use this view, enter the following query:

```
SELECT * FROM v$true_cache;
```

### The following example shows output on True Cache:

MY_DG_ID	REMOTE_DG_ID	DEST_ID	TRUE_CACHE_NAME	PRIMARY_NAME	STATUS
REMOTE_VERS	SION CON_ID				
2976625076	626116455	0	TCDB1	PRIMARYD	HEALTHY
23.0.0.0.0	0				

#### The following example shows output on a primary database:

MY_DG_ID	REMOTE_DG_ID	DEST_ID	TRUE_CACHE_NAME	PRIMARY_NAME	STATUS
REMOTE_VER	SION CON_ID				
626116455	2976625076	2	TCDB1	PRIMARYD	HEALTHY
23.0.0.0.0	0				
626116455	2499211322	3	TCDB2	PRIMARYD	HEALTHY
23.0.0.0.0	0				

### 5.1.1 V\$TRUE\_CACHE Columns

The following table describes the columns in the  $V\$TRUE\_CACHE$  view.

Table 5-1 V\$TRUE\_CACHE Columns

Column	Datatype	Description
MY_DG_ID	NUMBER	The Data Guard ID (DGID) that uniquely identifies the True Cache or primary database in the True Cache configuration
REMOTE_DG_ID	NUMBER	On True Cache, this is the primary database's DGID. On the primary database, it's the True Cache DGID.
DEST_ID	NUMBER	On True Cache, this is always 0. On the primary database, it's the corresponding destination ID (n) of the LOG_ARCHIVE_DEST_n initialization parameter. The LOG_ARCHIVE_DEST_n initialization parameter specifies the network name of the True Cache so that the primary database knows where to send online redo log blocks.
TRUE_CACHE_NAME	VARCHAR2(30)	The unique name of the True Cache (DB_UNIQUE_NAME in the PFILE)
PRIMARY_NAME	VARCHAR2(30)	The unique name of the primary database (DB_UNIQUE_NAME in the PFILE)
STATUS	VARCHAR2 (256)	Describes the current status of the True Cache. If no issues are found, it displays HEALTHY. Otherwise, it displays an error description. For example: ORA-01034: The Oracle instance is not available for use. Start the instance.
REMOTE_VERSION	VARCHAR2(18)	On True Cache, this is the database version of the primary database. On the primary database, this is the database version of the True Cache.
CON_ID	NUMBER	The root container ID

### **Related Topics**

V\$TRUE\_CACHE

# 5.2 Monitoring True Cache with the V\$TRUE\_CACHE\_STAT View

Use the  $V\$TRUE\_CACHE\_STAT$  view to monitor True Cache statistics, including apply lag, transport lag, and block fetch latency.

Query V\$TRUE\_CACHE\_STAT on True Cache. On the primary database this query returns no rows.

To use this view, enter the following query:

SELECT \* FROM v\$true\_cache\_stat;

### The following example shows output:

MY_DGID	REMOTE_DO	GID DE:	ST_ID NAME			VALUE	2
UNIT			TIME_COMPU	ΓED	DATA_TIME		CON_ID
3767970343			_		etch latency	y 3091

			•				

# 5.2.1 V\$TRUE\_CACHE\_STAT Columns

The following table describes the columns in the  $V\$TRUE\_CACHE\_STAT$  view.

Column	Datatype	Description
MY_DGID	NUMBER	Data Guard hash ID for True Cache
REMOTE_DGID	NUMBER	Data Guard hash ID for the primary database
DEST_ID	NUMBER	Log archive destination parameter identifier
		The value of this column is always 0.

Column	Datatype	Description
NAME	VARCHAR2(32)	Name of the metric:
		<ul> <li>apply lag - Apply lag is a measure of the degree to which the data in True Cache lags behind the data in the primary database, due to delays in propagating and applying redo to True Cache.</li> <li>list of blocks fetch latency - The average latency of True Cache while fetching blocks from the primary database in list of blocks fetch mode.</li> </ul>
		<ul> <li>multiblock fetch latency - The average latency of True Cache while fetching blocks from the primary database in multiblock fetch mode.</li> </ul>
		<ul> <li>prewarm progress - The current progress of True Cache prewarming its own buffer cache by proactively fetching the list of blocks remembered from the last warmed up state, that is, from the previous instance lifetime.</li> </ul>
		<ul> <li>single block fetch latency - The average latency of True Cache while fetching blocks from the primary database in single block fetch mode.</li> </ul>
		<ul> <li>transport lag - Transport lag is a measure of the degree to which the transport of redo to True Cache lags behind the generation of redo on the primary database. If there are one or more redo gaps on True Cache, the transport lag is calculated as if no redo has been received after the beginning of the earliest redo gap.</li> </ul>
		<b>Note:</b> The apply finish time and estimated startup time metrics are not meaningful on a True Cache and can be ignored.
VALUE	VARCHAR2(64)	Value of the metric
UNIT	VARCHAR2(32)	Unit of measurement
TIME_COMPUTED	VARCHAR2(32)	Local time on True Cache when the metric was computed
DATA_TIME	VARCHAR2(32)	Local time on True Cache when the data used to compute the metric was received
		The apply lag and transport lag metrics are computed based on data that is periodically received from the primary database. An unchanging value in this column across multiple queries indicates that True Cache is not receiving data from the primary database.
CON_ID	NUMBER	The ID of the container to which the data pertains.
		The value of this column is always 0 (CDB\$ROOT container).

#### **Related Topics**

V\$TRUE\_CACHE\_STAT

## 5.3 Using the Automatic Workload Repository for True Cache

You can use the Automatic Workload Repository (AWR) to gather performance statistics for True Cache.

AWR snapshots for True Cache are enabled by default. Snapshots are automatically captured hourly.

You can also manually create a snapshot. For example:

```
// Create snapshots (snap_id 0 means failure)
SELECT DBMS_WORKLOAD_REPOSITORY.CREATE_SNAPSHOT FROM dual;
```

To generate an AWR snapshot report, complete the following steps on either the primary database or the True Cache:

- Go to the \$ORACLE HOME directory and run the following script:
  - On True Cache:

```
@?/rdbms/admin/awrrpt.sql
```

On the primary database:

```
@?/rdbms/admin/awrrpti.sql
```

Specify whether you want an HTML or a text report. For example:

```
Enter value for report type: text
```

The output displays a list of available database identifiers and instance numbers.

3. If you're generating the report on the primary database, enter the database identifier (dbid) and instance number (inst\_num) for True Cache. For example:

```
Enter value for dbid: 3309173529
Using 3309173529 for database Id
Enter value for inst num: 1
```

To get the dbid for True Cache, run the following query on the True Cache:

```
SELECT DBMS_WORKLOAD_REPOSITORY.GET_AWR_ID() FROM dual;
```

This step is not required if you're generating the report on True Cache because the awrrpt.sql script automatically derives the dbid of the local node.

4. Specify the number of days for which you want to list snapshot IDs. For example:

```
Enter value for num_days: 2
```

The output displays a list of existing snapshots for the specified time range.

Specify beginning and ending snapshot IDs for the workload repository report. For example:

```
Enter value for begin_snap: 150
Enter value for end snap: 160
```

**6.** Enter a report name or accept the default report name. For example:

```
Enter value for report_name:
Using the report name awrrpt 1 150 160
```

# Using Oracle True Cache in Your Applications

When True Cache is configured, applications must decide whether to query data from True Cache or the primary database.

### 6.1 Methods for Connecting to True Cache

Applications can use True Cache in two ways.

- The application maintains two physical connections: one to the primary database and one
  to True Cache. Each connection has a database application service, and the application
  chooses which connection to use based on whether it's reading or writing. You can use this
  model with any existing client drivers and any programming language.
  - The application sends queries that don't need to see the most current data to True Cache through a True Cache database application service. The application sends other queries and updates to the primary database through the primary database application service.
- The application maintains one logical connection that uses the database application service for the primary database. The JDBC Thin driver (starting with Oracle Database 23ai) maintains physical connections to the primary database and True Cache. This model only works with Java applications.

The application switches between the primary database and True Cache without having to specify an instance name. The application uses special calls to flag the logical connection as read-only or read-write. If it's read-only, the query is sent to True Cache. Otherwise, it's sent to the primary database.

To enable the True Cache functionality for Java applications, set the value of the oracle.jdbc.useTrueCacheDriverConnection property to true. After you enable True Cache, the JDBC Thin driver uses the standard

java.sql.Connection.setReadOnly(boolean) and java.sql.Connection.isReadOnly() methods to mark a connection as read-only. By default, the read-only mode is false for a connection.

See the following technical architecture diagram for details and examples:

**True Cache Application** 

#### **Related Topics**

- Support for Oracle True Cache
- setReadOnly(boolean) method
- isReadOnly() method

### 6.2 Sample Java Code Using the JDBC Thin Driver

The JDBC method is illustrated by the following Java code using the JDBC Thin driver.

### **WARNING:**

Do not use this code in a production environment.

The core of this basic code is in the test1 function, which does the following:

- Creates a connection to the primary database by using the JDBC Thin driver with either a
  default user name and password or values that are specified on the command line when
  invoking the program.
- 2. Prints some basic information about the primary database connection to verify that the application is connected to the database.
- 3. Changes the isReadOnly connection parameter to TRUE to automatically switch the connection to True Cache and verify that it's connected to it.

```
import java.sql.*;
import java.io.*;
import java.util.*;
import java.util.logging.FileHandler;
import java.util.logging.Level;
import java.util.logging.Logger;
import oracle.jdbc.driver.OracleLog;
import oracle.jdbc.pool.OracleDataSource;
public class TrueCache {
  static String url primary = "jdbc:oracle:thin:@primary database host:1521/
SALES";
 static String user = "username";
 static String password = "password";
 public static void main(String args[]) {
    try {
     TrueCache t = new TrueCache();
     if(args != null && args.length >0 ) {
       url primary = args[0];
       user = args[1];
        password = args[2];
      t.test1();
    } catch (Exception e) {
      e.printStackTrace();
  }
  public void test1() throws SQLException {
    show("Basic test to connect to primary and True Cache");
      show("Get Connection from True Cache instance using primary db and
properties");
     OracleDataSource ods1 = new OracleDataSource();
      show("URL = " + url primary);
      ods1.setURL(url primary);
      ods1.setUser(user);
```

```
ods1.setPassword(password);
     ods1.setConnectionProperty("oracle.jdbc.useTrueCacheDriverConnection",
"true");
     Connection conn1 = ods1.getConnection();
     show("isReadonly " + conn1.isReadOnly());
     verifyConnection(conn1); // This is connected to Primary
     conn1.setReadOnly(true);
      show("isReadonly " + conn1.isReadOnly());
     verifyConnection(conn1); // This is connected to True Cache
     conn1.close();
    } catch (SQLException sqex) {
     show("test1 -- failed" + sqex.getMessage()+":"+sqex.getCause());
     sqex.printStackTrace();
    show("The end");
 public void verifyConnection(Connection conn) {
   try {
     Statement statement = conn.createStatement();
     ResultSet rs = statement.executeQuery("SELECT database role from
v$database");
     ResultSetMetaData rsmd = rs.getMetaData();
     int columnsNumber = rsmd.getColumnCount();
     rs.next();
     show("Database role : " + rs.getString(1));
     rs.close();
     ResultSet resultSet = statement.executeQuery("SELECT
SYS CONTEXT('userenv', 'instance name') as instance name"
          + ", SYS CONTEXT('userenv', 'server host')" + " as server host" +
", SYS CONTEXT('userenv', 'service name')"
         + " as service name" + ", SYS CONTEXT('USERENV', 'db unique name')"
+ " as db unique name" + " from sys.dual");
     resultSet.next();
     show("instance name : " + resultSet.getString("instance name"));
     show("server host : " + resultSet.getString("server host"));
     show("service name : " + resultSet.getString("service name"));
     show("db unique name : " + resultSet.getString("db unique name"));
     resultSet.close();
     statement.close();
    } catch (SQLException sqex) {
     show("verifyConnection failed " + sqex.getMessage());
    }
 public void show(String msg) {
   System.out.println(msq);
```

## 6.3 Sample Java Code for Applications Using a Native Connection to the Database

The following Java code illustrates how to use True Cache with applications that use an objectrelational mapping (ORM) framework.

This is another example of maintaining only one logical connection to a database application service running on the primary database and letting the driver handle the underlying physical connections. It shows how to get the underlying connections from the framework so you can set the necessary parameter.

### WARNING:

Do not use this code in a production environment.

- 1. Add the oracle.jdbc.useTrueCacheDriverConnection=true connection property to the connection URL in the persistence.xml file.
- 2. In the methods that need to use a True Cache connection, unwrap the session, use the dowork method to retrieve the underlying JDBC connection, and set the necessary readonly parameter for the connection. For example:

```
Session session = em.unwrap(Session.class);
session.doWork(new Work() {
   @Override
   public void execute(Connection con) throws SQLException {
      // if it is connected to primary, I want the connection to switch to
true cache now
      if(!con.isReadOnly()) {
         // The below code demonstrates the connection is to primary
now
         System.out.println("Query getting executed on:");
         Statement statement = con.createStatement();
         ResultSet rs = statement.executeQuery("SELECT database role from
v$database");
         System.out.println("Database role : " + rs.getString(1));
         rs.close();
         // Now switching the connections to true cache
         con.setReadOnly(true);
         // The below code demonstrates the connection is to true cache
now
         System.out.println("After set read only true, Query getting
executed on:");
         Statement statement2 = con.createStatement();
         ResultSet rs2 = null;
         rs2 = statement2.executeQuery("SELECT database role from
v$database");
         rs2.next();
```

```
System.out.println("Database role : " + rs2.getString(1));
    rs2.close()
}
}
});
```

### 6.4 Best Practices for Load Balancing in a Uniform Configuration

If multiple True Caches exist and serve the same database application service, the listener automatically distributes and load balances sessions to each cache. In a uniform configuration, the listener picks a True Cache randomly or based on load, and all True Caches cache the same data.

A uniform configuration uses runtime connection load balancing (CLB), which routes requests to the True Cache that offers the best performance. For this to work, all True Caches' REMOTE\_LISTENER parameters should point to the same listener, which is also the primary database's listener (whether it's single instance primary database's local listener or an Oracle RAC primary database's SCAN listener).

The application's JDBC URL should point to the primary database. Then the JDBC Thin driver creates one logical connection and multiple physical connections to the primary database and to each True Cache. Setting the <code>setReadOnly(true)</code> flag in the Java code reroutes connections to the True Caches automatically. The True Caches are registered with the primary database listener, and they also send their load statistics to the primary database listener. You should see an even distribution between True Caches.

To simplify configuration and avoid connection issues, consider using the LISTENER\_NETWORKS initialization parameter instead of specifying REMOTE\_LISTENER and LOCAL\_LISTENER separately. With LISTENER\_NETWORKS, all listeners within the same network name will cross-register. For example:

For more about configuring remote listeners and listener networks, see Prepare a PFILE for True Cache.

# Complementary Caching Features

True Cache can be combined with other Oracle Database features to improve performance.

### 7.1 Server-Side Result Set Cache

The server-side result cache is used to cache the results of the current queries, query fragments, and PL/SQL functions in memory. The cached results are used in future uses of the query, query fragment, or PL/SQL function.

The cached results stay in the result cache memory part of the SGA. A cached result is automatically invalidated whenever a database object used in its creation is successfully changed. See Tuning the Result Cache for more information about configuring the server-side result set cache.

To enable the server-side result cache on True Cache, issue the following command on the primary database:

```
ALTER TABLE table name RESULT CACHE (STANDBY ENABLE);
```

Support for server-side result set caching is available for both JDBC Thin and JDBC Oracle Call Interface (JDBC OCI) drivers.

#### **Related Topics**

Using the Result Cache on Physical Standby Databases

### 7.2 KEEP Buffer Pool

You can use the KEEP buffer pool to keep frequently accessed tables persistent in the buffer pool.

### 7.2.1 Overview of Using the KEEP Buffer Pool with True Cache

You can assign different objects to the KEEP buffer pool on different True Caches.

At a high level, this involves the following steps:

- 1. Configure DB KEEP CACHE SIZE on True Cache.
- 2. Assign objects on True Cache to the KEEP buffer pool.

As with the primary database, when an object is assigned to the KEEP buffer pool on True Cache, the object's blocks are loaded for a query and then kept in the KEEP buffer pool. When new data is inserted into the object on the primary database, that new data is automatically propagated to the KEEP buffer pool on True Cache through the redo apply mechanism.

To propagate direct load data to True Cache, specify the LOGGING clause in the corresponding DDL or DML, or alter the corresponding object property to LOGGING. The LOGGING clause lets you specify whether certain operations will be logged in the redo log file (LOGGING) or not (NOLOGGING).

#### **Related Topics**

- Configuring the KEEP Pool
- logging\_clause

### 7.2.1.1 Supported Objects

The KEEP mechanism only tracks objects that have physical data segments.

To see if an object can be tracked, make sure it has a <code>DATA\_OBJECT\_ID</code> in the <code>DBA\_OBJECTS</code> view.

#### **Related Topics**

DBA OBJECTS

### 7.2.1.2 How True Cache Works with the Primary Database Buffer Cache

By default, marking something KEEP on the primary database also marks it KEEP on True Cache.

To prevent objects that are intended to be KEEP objects only on the primary database from filling up the True Cache KEEP buffer pool, you can use the DBMS\_CACHEUTIL.TRUE\_CACHE\_KEEP procedure to mark objects as KEEP on True Cache. DBMS\_CACHEUTIL.TRUE\_CACHE\_KEEP takes precedence and overrides objects that are marked as KEEP on the primary database.

Also consider the following points:

- ALTER TABLE KEEP assignments on the primary database are persistent because ALTER
  TABLE is a DDL. The DBMS\_CACHEUTIL.TRUE\_CACHE\_KEEP procedure isn't persistent when
  True Cache restarts.
- You can't use the DBMS\_CACHEUTIL.TRUE\_CACHE\_UNKEEP procedure to unkeep a primary
   ALTER TABLE KEEP assignment. Instead, either don't configure DB\_KEEP\_CACHE\_SIZE on
   True Cache or assign a different object with DBMS\_CACHEUTIL.TRUE\_CACHE\_KEEP on True
   Cache.
- All scans on True Cache use the CACHE path instead of the direct (NOCACHE) path, except temporary tables that are local to True Cache.

### 7.2.2 Configuring DB KEEP CACHE SIZE on True Cache

To configure the KEEP buffer pool on True Cache, set the DB\_KEEP\_CACHE\_SIZE initialization parameter to a large size (such as 10 GB).

#### For example:

ALTER SYSTEM SET DB\_KEEP\_CACHE\_SIZE=size SCOPE=BOTH;

#### **Related Topics**

- DB KEEP CACHE SIZE
- Setting or Changing Initialization Parameter Values

### 7.2.3 Assigning Objects to the KEEP Buffer Pool for True Cache

After configuring the KEEP buffer pool, assign the object to the KEEP buffer pool for True Cache.

To do this, call the DBMS CACHEUTIL. TRUE CACHE KEEP() procedure on True Cache.

#### **Example: Nonpartitioned Object**

```
EXECUTE DBMS_CACHEUTIL.TRUE_CACHE_KEEP('SYS', 'TABLE1');
```

#### **Example: Partition of a Partitioned Object**

```
EXECUTE DBMS CACHEUTIL.TRUE CACHE KEEP('SYS', 'TABLE2', 'TABLE2 PART1');
```

### 7.2.3.1 TRUE\_CACHE\_KEEP Procedure

When you call this procedure on True Cache, it assigns the object to the KEEP buffer pool on that cache.

To use this procedure, the <code>DB\_KEEP\_CACHE\_SIZE</code> initialization parameter must be configured on True Cache.

#### **Syntax**

```
DBMS_CACHEUTIL.TRUE_CACHE_KEEP(
schema IN VARCHAR2,
obj IN VARCHAR2,
partition IN VARCHAR2 := NULL);
```

#### **Parameters**

#### Table 7-1 TRUE\_CACHE\_KEEP Procedure Parameters

Parameter	Description	
schema	The name of the schema for the object.	
obj	The name of the object.	
partition	<ul> <li>If the object is not partitioned, then this is NULL.</li> <li>If the object is partitioned, use the name of the partition segment.</li> <li>If it's a composited partitioned object, use the name of the subpartition segment.</li> </ul>	

### **Related Topics**

TRUE\_CACHE\_KEEP Procedure

### 7.2.4 Removing an Object's KEEP Buffer Pool Assignment for True Cache

You can use DBMS\_CACHEUTIL.TRUE\_CACHE\_UNKEEP() to remove objects from the KEEP buffer pool.

Note that the block is not removed immediately. Instead, it will be naturally aged out as new blocks for other objects are brought into the KEEP buffer pool. Also, the KEEP buffer pool assignment on True Cache is only remembered while True Cache is up.

#### **Example: Nonpartitioned Object**

```
EXECUTE DBMS CACHEUTIL.TRUE CACHE_UNKEEP('SYS', 'TABLE1');
```

### **Example: Partition of a Partitioned Object**

```
EXECUTE DBMS CACHEUTIL.TRUE CACHE UNKEEP('SYS', 'TABLE2', 'TABLE2 PART1');
```

### 7.2.4.1 TRUE CACHE UNKEEP Procedure

When an object on True Cache no longer needs to be in the KEEP buffer pool, use this procedure to remove the object's KEEP assignment.

#### **Syntax**

```
DBMS_CACHEUTIL.TRUE_CACHE_UNKEEP(
schema IN VARCHAR2,
obj IN VARCHAR2,
partition IN VARCHAR2 := NULL);
```

#### **Parameters**

#### Table 7-2 TRUE CACHE UNKEEP Procedure Parameters

Parameter	Description	
schema	The name of the schema for the object.	
obj	The name of the object.	
partition	<ul> <li>If the object is not partitioned, then this is NULL.</li> </ul>	
	<ul> <li>If the object is partitioned, use the name of the partition segment.</li> </ul>	
	<ul> <li>If it's a composited partitioned object, use the name of the subpartition segment.</li> </ul>	

#### **Related Topics**

TRUE\_CACHE\_UNKEEP Procedure

### 7.2.5 Viewing a List of KEEP Objects on True Cache

Use the V\$TRUE\_CACHE\_KEEP view to see which objects are assigned to the KEEP buffer cache for True Cache.

#### **Example 1**

#### **Example 2**

### 7.2.5.1 V\$TRUE\_CACHE\_KEEP Columns

The following table describes the columns in the V\$TRUE CACHE KEEP view.

Column	Description	
TS_NUMBER	The tablespace number.	
DATA_OBJECT_ID	The dictionary object number of the segment that contains the object.	
CON_ID	The ID of the container to which the data pertains. Possible values include:	
	1: This value is used for rows containing data that pertain to only the root.	
	<ul> <li>n: Where n is the applicable container ID for the rows containing data.</li> </ul>	

### 7.3 Database Smart Flash Cache

If the data that you want to cache doesn't fit in memory, you can expand the capacity of True Cache by adding flash devices. You do this by configuring Database Smart Flash Cache.

To enable Database Smart Flash Cache, see Configuring Database Smart Flash Cache.

### Note:

When configuring Database Smart Flash Cache on True Cache, spilling TDE encrypted data to local flash devices is not supported. If a data block is TDE encrypted on the primary database, it stays in the DRAM buffer cache on True Cache.

# **Deleting True Cache**

You can delete True Cache with Oracle DBCA or manually.

### 8.1 Using Oracle DBCA to Delete True Cache

You can use Oracle DBCA to clean up the True Cache services and delete True Cache.

### 8.1.1 Cleaning Up the True Cache Services from the Primary Database

To delete True Cache, you need to clean up its corresponding services on the primary database.

Run the following command on the primary database to delete all the services that correspond to the True Cache that you're planning to delete.

```
ORACLE_HOME/bin/dbca -configureDatabase -cleanupTrueCacheInstanceService - sourceDB primary_sid_or_db_unique_name -trueCacheConnectString true_cache_easy_connect_string -serviceName primary_service_name - trueCacheServiceName true cache service name -silent
```

#### Example:

```
$ORACLE_HOME/bin/dbca -configureDatabase -cleanupTrueCacheInstanceService -
sourceDB primdbli -trueCacheConnectString tc.example.com:1522/
tcdb1.example.com -serviceName sales -trueCacheServiceName sales tc -silent
```

For descriptions of the parameters, see configureDatabase.

### 8.1.2 Deleting True Cache from the True Cache Node

Run the following command to delete True Cache from the True Cache node.

```
ORACLE_HOME/bin/dbca -deleteDatabase -sourceDB true_cache_sid_or_db_unique_name -silent
```

#### Example:

\$ORACLE HOME/bin/dbca -deleteDatabase -sourceDB tcdb1 -silent

# 8.2 Deleting True Cache Manually

To delete True Cache manually, use the following commands.

```
connect / as SYSDBA;
shutdown immediate;
startup mount exclusive restrict;
drop true cache;
```

### Note:

This does *not* drop the primary database. It deletes the True Cache SPFILE; drops the True Cache control, standby log, and temporary files; and removes LOG\_ARCHIVE\_DEST entries from the primary database.

9

# Deploying Oracle True Cache with Oracle Global Data Services

You can deploy Oracle True Cache with Oracle Database Global Data Services (GDS) to manage workload routing, dynamic load balancing, and service failover across multiple True Caches and other database replicas.

### 9.1 Global Data Services Overview

Oracle Global Data Services (GDS) provides workload routing based on load, locality, or lag, as well as service failover across replicas.

This helps enterprises maximize application performance, mitigate downtime during planned and unplanned outages, and manage resources of replicas with one interface.

GDS supports Oracle Databases, standby databases, GoldenGate replicated databases, Oracle globally distributed databases, True Caches, and more.

You create and manage the GDS configuration and global services with the GDSCTL command-line interface, which is similar to the SRVCTL command-line interface used to manage an Oracle Real Application Clusters (Oracle RAC) database and its services.

A GDS configuration includes the following components:

- The GDS catalog stores configuration data for a GDS configuration. The GDS catalog
  resides in an Oracle Database. For large-scale GDS configurations, Oracle recommends
  that the GDS catalog be hosted outside the databases in the GDS configuration.
- A GDS region is a group of databases, True Caches, and clients in close network
  proximity (for example, east and west). For high availability, assign a buddy region for each
  region. Only one buddy region is allowed for each region.
- A **global service manager (GSM)** is the central software of GDS, providing service-level load balancing, failover, and centralized management of services in the GDS configuration. For high availability, include two GSMs in each region.
- A GDS pool is a group of databases and True Caches that offer a common set of global services (for example, human resources and sales). A region can contain multiple GDS pools, and these pools can span multiple regions. A database or True Cache can only belong to a single GDS pool. All databases and True Caches that provide the same global service must belong to the same pool.
- Global services are functionally similar to the local database application services that are provided by single-instance or Oracle RAC databases. The main difference between global services and local services is that global services span the instances of multiple databases, whereas local services span the instances of a single database.
- A client connection pool, such as the Oracle universal connection pool (UCP) JDBC connection pool that can receive load balancing recommendations is required for global runtime connection load balancing.
- An Oracle Notification Service (ONS) server is located with each GSM. All ONS servers
  in a region are interconnected in an ONS server network. The GSMs create runtime load

balancing advisories and publish them to the client connection pool through the ONS server network.

#### **Related Topics**

Introduction to Global Data Services

### 9.2 True Cache Integration with Global Data Services

True Cache provides the following integrations with Oracle Global Data Services (GDS).

- GDS provides the -role TRUE CACHE option for global services.
- The True Cache application programming model using JDBC SetReadOnly() supports global services.
- GDS provides load balancing and service failover between multiple True Caches.

### 9.3 Configuring Global Data Services for True Cache

These are the basic steps to configure Oracle Global Data Services (GDS) for True Cache.

For additional GDS configuration options, see Configuring the Global Data Services Framework.

### 9.3.1 Set Up the Environment

Before you install any software, review the hardware, network, operating system, and other software requirements for Linux.

- The primary database and all True Caches in the GDS pool must be able to reach (in both directions) every global service manager's (GSM's) listener and Oracle Notification Service (ONS) ports. The GSM listener ports and ONS ports must also be opened to the application tier, the primary database and all True Caches in the GDS pool, the GDS catalog, and all other GSMs.
- The TNS listener port (default: 1521) of the primary database and all True Caches in the GDS pool must be opened (in both directions) to the GSMs and the GDS catalog.
- If you run GDSCTL from a separate machine, you also must have a port opened (in both directions) from that machine directly to the primary database and all True Caches in the GDS pool.

For detailed information about memory, physical storage, kernel versions and packages required by Global Data Services see Database Installation Guide for Linux.

#### **Related Topics**

- Planning an Installation
- Oracle Notification Service (ONS)

### 9.3.2 Install the Global Service Manager Software

The global service manager (GSM) is the central component of the GDS framework, and it includes the GDSCTL command-line interface.

Install at least one GSM in each region. For high availability, include two GSMs in each region.

To install GSMs, see the following topics in the *Oracle Database Global Data Services Concepts and Administration Guide*:

- What You Need to Know About Installing a Global Service Manager
- Installing a Global Service Manager

### 9.3.3 Configure True Cache

Create True Caches using Oracle DBCA or manually.

You don't need to configure the True Cache application services using Oracle DBCA or manually, because you will configure these as global services later using GDS.

#### For Oracle DBCA:

- 1. Prerequisites
- 2. Creating True Cache with DBCA

For a manual configuration:

- 1. Prerequisites
- 2. Creating True Cache Manually

## 9.3.4 Configure the GDS Catalog Database

Configure the database where the GDS catalog will reside.

In addition to these steps, ensure that the GDS catalog is protected for high availability and disaster recovery.

1. Create the GDS administrator account and grant GSMADMIN ROLE privileges.

#### For example:

```
CREATE USER gsm_admin IDENTIFIED BY ****

GRANT gsmadmin role TO gsm admin
```

Unlock the GDS system accounts on the catalog database.

```
sqlplus / as SYSDBA

ALTER USER gsmuser ACCOUNT UNLOCK IDENTIFIED BY ****

ALTER USER gsmcatuser ACCOUNT UNLOCK IDENTIFIED BY ****

3. Start GDSCTL.

gdsctl
```

#### **Related Topics**

What You Need to Know About Creating the Global Data Services Catalog

### 9.3.5 Create the GDS Catalog

Create the GDS catalog on the primary database or a database outside the GDS configuration.

For large-scale GDS configurations, Oracle recommends that the GDS catalog be hosted outside the databases in the GDS configuration.

```
create catalog -database db_name -region region_list -user user_name/password
For example:
create catalog -database gdscatdb -region DCX, DC_Y -user gsmcatuser/****
```

If you don't specify a region when setting up the catalog, then a default region named REGIONORA is created. You can optionally add more regions later.

### 9.3.6 Set Up Global Service Managers

Before you can start a global service manager (GSM), you need to register the GSM with the GDS catalog.

For high availability, include two GSMs in each region.

1. Add a GSM to the region.

```
add gsm -gsm gsm_name -pwd password -catalog catalog_db_name -region region_name
```

### For example:

```
add gsm -gsm gsm_dc_x1 -catalog primdb1i -pwd **** -region DC_X
```

You can run this command only on the system that hosts the GSM. Repeat the command for each GSM on each system that runs the GSM.

2. Start the GSM.

```
start gsm -gsm gsm_name
```

#### For example:

```
start gsm -gsm gsm dc x1
```

3. Check the status of the GSM.

status gsm

### 9.3.7 (Optional) Set Up Regions

If you didn't already set up regions when creating the GDS catalog, add a GDS region for each data center.

For high availability, assign a buddy region for each region. Only one buddy region is allowed for each region.

At least one GSM must be added and running before you can add regions.

```
add region -region region_list

modify region -region region_name -buddy region_name

For example:
add region -region DC_X, DC_Y

modify region -region DC X -buddy DC Y
```

### 9.3.8 Set Up the GDS Pool

Add a GDS pool and then add the primary database and True Caches to the pool.

```
add gdspool -gdspool db_pool_list

add database -connect db name -region region name -gdspool gds pool name
```

#### For example:

```
add gdspool -gdspool sales

add database -connect primdbli -pwd **** -gdspool sales -region DC_X //
primary

add database -connect tcdbl -pwd **** -gdspool sales -region DC_X // True
Cache
```

### Note

If you receive the following warning when you add a True Cache to a GDS pool that has existing True Caches and services running, you can ignore it: ORA-44311:  $service\_name\_not\_running$ .

### 9.3.9 Set Up Global Services

Create and start the global database application services for the primary database and True Caches.

### Note:

If the application uses the JDBC programming model, both the primary database service and True Cache service names must be fully qualified with the domain name (for example, sales.example.com and sales\_tc.example.com). This is because GDS has a default domain name and is different from the database's domain\_name parameter. This also limits the fully qualified service name to a maximum of 64 characters.

### Note:

The PDB name is required to create a service for a PDB. If you don't specify the PDB name, the service is created in CDB\$ROOT.

1. Create the global services for the primary database.

```
add service -service service_name.domain_name -gdspool gdspool_name - preferred dbname list -pdbname primary pdb name -role primary
```

#### For example:

add service -service sales.example.com -gdspool sales -preferred primdbli -pdbname sales pdb -role primary

2. Create the global services for True Cache.

```
add service -service service_name.domain_name -gdspool gdspool_name -preferred_all -pdbname primary_pdb_name -clbgoal SHORT -rlbgoal SERVICE_TIME -locality LOCAL_ONLY -region_failover -lag lag_value -role true_cache -failover_primary
```

#### For example:

add service -service sales\_tc.example.com -gdspool sales -preferred\_all pdbname sales\_pdb -clbgoal SHORT -rlbgoal SERVICE\_TIME -locality
LOCAL\_ONLY -region\_failover -lag 15 -role true\_cache -failover\_primary

The -failover primary option requires the patch for bug 36740927.

- 3. Associate the True Cache service with the primary database service.
  - For True Cache and single instance primary databases, use the DBMS\_SERVICE\_PRVT PL/SQL package.

On the primary database, connect to the PDB first. The following example uses the sales.example.com and sales tc.example.com services.

```
DECLARE

db_params sys.dbms_service_prvt.svc_parameter_array;
cl_params sys.dbms_service_prvt.svc_parameter_array;
BEGIN

-- modify an already existing primary service SALES to set the
TRUE_CACHE_SERVICE attribute and associate with SALES_TC

db_params('true_cache_service') :='sales_tc.example.com';
DBMS_SERVICE_PRVT.MODIFY_SERVICE('sales.example.com', cl_params, db_params, FALSE, 1);
END;
```

• For Oracle RAC primary databases, use the srvctl command line utility with the - global override option to alter global services.

If you configure True Cache with Oracle DBCA, use the following command:

```
srvctl add service -db primary_db_unique_name -service
primary_db_service_name.domain_name -preferred primary_db_instance_list
-pdb primary pdb name -global override
```

### For example:

srvctl add service -db primdb1i -service sales.example.com -preferred
primdb1i1,primdb1i2 -pdb sales pdb -global override

For manual configuration options, see Create Database Application Services on the Primary Database.

Also disable the True Cache service on the cluster where it was added to prevent errors when stopping and restarting the primary database services. For example:

```
srvctl start service -d primdbli -s sales_tc.example.com
srvctl stop service -d primdbli -s sales_tc.example.com
srvctl disable service -d primdbli -s sales_tc.example.com
```

This doesn't affect standby databases or True Caches because they run outside the cluster where the True Cache service is disabled. The disabled status is not stored in the primary dictionary and <code>DBA\_SERVICES</code>, but only in Cluster Ready Services (CRS), and only in the cluster where the True Cache service was added. Other databases outside the cluster can start the service with <code>DBMS\_SERVICE.START\_SERVICE</code> and aren't affected by this setting.

#### 4. Start the services.

```
start service -service service_name.domain_name
```

The following example starts the services on the primary database and on all True Caches:

```
start service -service sales.example.com
start service -service sales tc.example.com
```

### 9.3.9.1 Global Service Best Practices for JDBC

To use global services with the JDBC setReadOnly (TRUE) flag, follow these best practices.

- Create the global services for the primary database and True Cache using fully qualified names (for example, sales.example.com and sales\_tc.example.com). This is because GDS has a default domain name and is different from the database's domain\_name parameter. This also limits the fully qualified service name to a maximum of 64 characters.
- Use DBMS\_SERVICE\_PRVT instead of DBMS\_SERVICE to associate the True Cache service with the primary database service.

### 9.3.9.2 GDSCTL add service Options

This table describes the GDSCTL add service options that apply to True Cache.

Option	Description		
-available dbname_list	Specify a comma-delimited list of available databases or True Caches on which the service runs if the preferred ones are not available. You can't specify a list of available instances, only databases and True Caches. You can use the modify service command with the - server_pool parameter to specify instance-level preferences.		
	The list of available databases or True Caches must be mutually exclusive with the list of preferred ones.		
	You cannot use this option with the -preferred_all option.		
-clbgoal {SHORT   LONG}	For True Cache services, set the connection load balancing goal to SHORT for runtime load balancing.		
-failover_primary	If the <code>-role</code> is <code>TRUE_CACHE</code> , you can use this option to enable the service to failover to the primary database if no True Caches are available. Also include the primary database in the <code>-preferred</code> or <code>-available</code> list, or use the <code>-preferred_all</code> option.		
	Note:  The -failover_primary option requires the patch for bug 36740927.		
	requires the patch for bug 36740927.		
-gdspool gdspool_name	Specify the name of the global data services pool to which you want to add a service. If the pool name is not specified and there is only one gdspool with access granted to the user, then the gdspool with access granted is used as the default gdspool.		
-lag {lag_value   ANY}	Specify the maximum acceptable lag for the service in seconds. Enter ANY if there is no upper threshold. If a True Cache falls behind the primary database beyond the specified lag time, the service stop forwarding requests to that True Cache until it catches up.  The default value for lag, if not specified, is ANY.		
-locality {ANYWHERE   LOCAL_ONLY}	For True Cache services, set the locality to LOCAL_ONLY. This indicates that GDS only routes to True Caches in the same region, regardless of load. Use this option together with -region_failover so that client connections and requests are routed to another region if all True Caches in a region have failed.		

 $\hbox{-pdbname} \ \ primary\_pdb\_name \ \ \hbox{Enter the primary pluggable database (PDB) name}.$ 

The PDB name is required to create a service for a PDB. If you don't specify the PDB name, the service is created in CDB\$ROOT.

Option	Description
-preferred dbname_list	Specify a comma-delimited list of preferred databases or True Caches on which the service runs. You can't specify preferred instances, only databases and True Caches. You can use the modify service command to specify instance-level preferences.
	The list of preferred databases or True Caches must be mutually exclusive with the list of available ones.
	You cannot use this option with the -preferred_all option.
-preferred_all	For True Cache services, indicates that this service will be started on all existing and future True Caches and, if used with - failover_primary, the primary database.
-region_failover	Indicates that the service is enabled for region failover. You can only use this option when you specify LOCAL_ONLY for the -locality option.
-rlbgoal {SERVICE_TIME   THROUGHPUT}	For True Cache services, set the runtime load balancing goal to SERVICE_TIME to balance connections by response time instead of by throughput.
-role {PRIMARY]   [PHYSICAL_STANDBY	Specify the database role that the database must have for this service to start on that database.
TRUE_CACHE}	For primary database services, use PRIMARY.
	For True Cache services, use TRUE_CACHE. This ensure that the service only runs on other True Caches, not on the primary database.

Description

-service service name.domain name

Specify the name of the global service.

### Note:

If the application uses the JDBC programming model, both the primary database service and True Cache service names must be fully qualified with the domain name (for example, sales.example.com and sales\_tc.example.com). This is because GDS has a default domain name and is different from the database's domain\_name parameter. This also limits the fully qualified service name to a maximum of 64 characters.

A global service name must be unique within a GDS pool and when qualified by domain, must also be unique within a GDS configuration. A global service cannot be created at a database if a local or global service with the same name already exists at that database.

A global service name can contain alphanumeric characters, underscore (\_), and period (.). The first character must be alphanumeric. The maximum length of a global service name is 64 characters. The maximum length of a domain qualified global service name is 250 characters.

An Oracle Net connect descriptor used to connect to a global service must contain a domain qualified service name.

For True Cache service names, see Best Practices for Database Application Services.

### Note:

This table lists the add service options that are specific to True Cache. For the full syntax and parameters, see add service in the *Oracle Database Global Data Services Concepts and Administration Guide*.

### 9.3.10 Set Up the Client TNS Entry

Update the tnsnames.ora files for the primary database and True Caches based on region.

#### **Example 9-1 Primary Database**

In this example, the ADDRESS\_LIST points to the GSM in the region where the primary database is located.

```
sales =
(DESCRIPTION = (CONNECT_TIMEOUT=90) (RETRY_COUNT=30) (RETRY_DELAY=3)
(TRANSPORT CONNECT TIMEOUT=3)
```

```
(FAILOVER=ON)
  (ADDRESS_LIST = //Lists DC_X's GSM listeners because primary is in DC_X
   (LOAD_BALANCE=ON)
   (ADDRESS = (PROTOCOL = TCP) (HOST = gsm_dc_x1) (PORT = 1572)))
  (CONNECT_DATA =
        (SERVICE_NAME = sales.example.com)))
```

#### **Example 9-2** True Cache

In this example, the first ADDRESS\_LIST points to the GSM in the region where the True Cache is located. The second ADDRESS\_LIST points to the GSM in the associated buddy region.

```
sales_tc =
(DESCRIPTION = (CONNECT_TIMEOUT=90) (RETRY_COUNT=30) (RETRY_DELAY=3)
(TRANSPORT_CONNECT_TIMEOUT=3)
(FAILOVER=ON)
  (ADDRESS_LIST = //DC_X's GSM listeners
  (LOAD_BALANCE=ON)
    (ADDRESS = (PROTOCOL = TCP) (HOST = gsm_dc_x1) (PORT = 1572)))
(ADDRESS_LIST = //buddy DC_Y's GSM listeners
  (LOAD_BALANCE=ON)
    (ADDRESS = (PROTOCOL = TCP) (HOST = gsm_dc_y1) (PORT = 1572)))
(CONNECT_DATA =
    (SERVICE_NAME = sales_tc.example.com) (REGION=DC_X))) // this client is
in DC_X
```

### 9.4 True Cache Restrictions with Oracle Global Data Services

Deploying True Cache with Oracle GDS has the following restrictions.

- When adding True Cache services in GDSCTL, the -failover\_primary option requires the patch for bug 36740927.
- If the application uses the JDBC programming model, both the primary database service and True Cache service names must be fully qualified with the domain name (for example, sales.example.com and sales\_tc.example.com). This is because GDS has a default domain name and is different from the database's domain\_name parameter. This also limits the fully qualified service name to a maximum of 64 characters.

A

# True Cache Error Messages

View error messages that you might encounter when using True Cache.

Select an error message to read the full description in the Error Help Portal.

- ORA-61850, Oracle version mismatch between primary database and True Cache.
- ORA-61851, True Cache instance does not allow string operation.
- ORA-61852, CREATE TRUE CACHE failed.
- ORA-61853 Cannot start True Cache.
- ORA-61854 Cannot start True Cache with non True Cache control file.
- ORA-61855 Invalid TRUE\_CACHE\_CONFIG attribute.
- ORA-61856 True Cache requires a valid parameter value for string.
- ORA-61857 Communication with the primary failed.
- ORA-61858 Unable to translate FAL\_SERVER initialization parameter string.
- ORA-61859 There was an error when executing a remote procedure call (op: string-stringstring) at primary server string.
- ORA-61860 True Cache instance is being shutdown because it has been disconnected from the primary for too long.
- ORA-61861 Unable to receive redo since standby redo log is not available.
- ORA-61862 String is not configured as a multitenant database.
- ORA-61863 True Cache could not be started because there was a configuration parameter mismatch with the primary. Restart the database.
- ORA-61864 True Cache failed to read metadata from the primary.
- ORA-61865 The TNS alias string could not be translated.
- ORA-61866 Some static parameters (string) differed from the value in the primary database. These parameters have been fixed and the database will be shut down.
- ORA-61867 Oracle True Cache failed to restart. Shutting down.
- ORA-61868 True Cache entry corresponding to the hash ID string not found in a LOG\_ARCHIVE\_DEST\_n parameter.
- ORA-61869 Unable to connect to True Cache.
- ORA-61870 True Cache requires ARCHIVELOG mode to be enabled at the primary database.
- ORA-61871 Cannot fetch data block from the primary database (file # string, block # string).
- ORA-61872 The string command in pluggable database string failed because some process is keeping a lock on it for too long. True cache will be restarted.
- ORA-61873 True Cache could not be started because the system parameter 'string' is different in the PRIMARY database. Remove the parameter from the True Cache initialization file.

- ORA-61874 Cannot fetch data block from the primary database (file # string, block # string).
- ORA-61875 There was a failure adding the system parameter LOG\_ARCHIVE\_DEST\_n at the primary database. True Cache database cannot be opened without it.
- ORA-61876 Failed to open True Cache because the primary database is configured for shared server.
- ORA-61877 True Cache recovery lags too far behind, exceeding string seconds.
- ORA-61878 PDB (con\_id:string) is not open on the primary database.
- ORA-61879 db\_keep\_cache\_size is not configured on True Cache.
- ORA-61880 This operation (string) is only allowed on True Cache instance.
- ORA-61881 Failed to open True Cache because there has been an error reading metadata (string) from the primary database string.
- ORA-61882 Cannot start Free Edition True Cache because the maximum number of configured Free Edition True Caches (string) for the database has been reached already.

B

# True Cache Database Statistics Descriptions

The following table describes the True Cache-related statistics stored in the V\$SESSTAT and V\$SYSSTAT views.

For details on classes and <code>TIMED\_STATISTICS</code>, see Statistics Descriptions.

**Table B-1 Database Statistics Descriptions** 

Name	Class	Description	TIMED_STATIS TICS
TrueCache: block requests to preferred primary	264	Number of block fetch requests sent to the preferred primary Oracle RAC instance with object or undo affinity.	
TrueCache: block requests to primary	264	Total number of block fetch requests sent to the primary database.	
True Cache: message roundtrip time data send	256	Cumulative, elapsed, round-trip messaging time in microseconds of this primary instance sending data blocks to True Cache.	
True Cache: message roundtrip time request send	256	Cumulative, elapsed, round-trip messaging time in microseconds of this True Cache sending data block fetching requests to the primary database.	
True Cache: message count data send	256	Total number of messages this primary instance sends to True Cache for returning data blocks.	
True Cache: message count request send	256	Total number of messages this True Cache sends to the primary database for requesting data blocks.	
True Cache potentially current buffer made current	264	Count of data blocks arriving at True Cache as potentially current buffers due to timing conditions, and later confirmed to be real current buffers, so redo will continue to apply.	
True Cache potentially current buffer made CR	264	Count of data blocks arriving at True Cache as potentially current buffers due to timing conditions, and later deemed to be good only as consistent read buffers, so they will be aged out.	

C

# True Cache Wait Events

The following True Cache-related wait events are used for block fetching.

Table C-1 Wait Events

Wait Event	Class
True Cache: single block fetch	User I/O
True Cache: multiblock fetch	User I/O
True Cache: list of blocks fetch	User I/O

# Licensing for True Cache

True Cache licensing is based on the edition of Oracle Database that you're using for both the primary database and True Cache.

See Permitted Features, Options, and Management Packs by Oracle Database Offering in the Oracle Database Licensing Information User Manual.

Е

# Troubleshooting True Cache

Follow these recommendations if you run into issues when configuring or using True Cache.

### E.1 Rerunning Oracle DBCA

If you run into issues when configuring True Cache with Oracle DBCA, you need to clean up the True Cache node and then rerun DBCA.

### E.1.1 Rerunning Oracle DBCA After Creating True Cache

If you need to rerun Oracle DBCA after creating True Cache, clean up the True Cache node first.

If you don't do the cleanup, DBCA might say that the instance already exists.

- Shut down True Cache if it was started during the creation. See Shutting Down True Cache.
- 2. Remove any newly created files in the <code>\$ORACLE\_HOME/dbs</code> directory for True Cache. File names contain the True Cache name.
- 3. If you used a Transparent Data Encryption (TDE) auto-login wallet, delete the wallet and auto-login file in the \$ORACLE BASE/admin/true cache name/wallet root/tde/ directory.
- 4. Create True Cache again. See Creating True Cache with DBCA.

# E.1.2 Rerunning Oracle DBCA After Configuring True Cache Database Application Services

If you need to rerun Oracle DBCA after configuring True Cache database application services, you might need to delete the True Cache service from the primary pluggable database (PDB) using the DBMS\_Service package.

#### Example error message:

```
[DBT-19958] Database service 'trueCacheServiceName'
```

- For services that are specific to a PDB, connect to the specific PDB, or set the correct PDB container in your session.
- Connect to True Cache and stop the True Cache service on True Cache if it's running.

```
EXEC DBMS SERVICE.STOP SERVICE('trueCacheServiceName');
```

3. Delete the service on the primary database using DBMS SERVICE. DELETE SERVICE.

```
EXEC DBMS SERVICE.DELETE SERVICE('trueCacheServiceName');
```

4. Configuration the True Cache application service again. See Configuring True Cache Database Application Services with DBCA.

# E.2 Preventing SRVCTL from Restarting True Cache Services for Oracle RAC Primary Databases

To prevent errors when stopping and restarting primary database services for Oracle RAC database, disable the True Cache service on the cluster where it was added.

The following errors might occur:

```
PRCD-1133: failed to start services for database
PRCR-1095: Failed to start resources using filter
CRS-2501: Resource 'ora.primary db.true cache service.svc' is disabled
```

To prevent these errors, disable the True Cache service on the cluster where it was added. For example:

```
srvctl disable service -d primdbli -s sales tc
```

This doesn't affect standby databases or True Caches because they run outside the cluster where the True Cache service is disabled. The disabled status is not stored in <code>DBMS\_SERVICE/service\$</code>, but only in Cluster Ready Services (CRS), and only in the cluster where the True Cache service was added. Other databases outside the cluster can start the service with <code>DBMS\_SERVICE.START\_SERVICE</code> and aren't affected by this setting.
